It enables you to simply click on the element you wish to view and it displays information such as handle's name, the class it belongs to, if it contains text, parent window as well as its RECT structure. **B**enefits and Features **E**asy to use application **T**

The software enables you to retrieve the information that defines a window or a window handle, with a simple click. You can enable one of the two info grabbing modes. Select the Finder tool

and drag and drop it on top of the instance you wish to analyze, or the Watch cursor function that extracts information from whichever handle lies at the tip of your cursor. You can view the metadata you have selected as a summary that contains the basic parameters, or as a detailed list. The software displays data such as handle name, RECT structure, position in the parent instance, control ID, window style, size, resolution and whether or not it contains Unicode language. This can help you develop your own handles, as solution to runtime errors, for instance.

**Tree structure** The Window Tree view displays all the windows opened on your desktop in a structure of nodes, along with the order in which they were accessed and the relations between them. You can view all the currently running processes, as well as those that run in the background. For a simplified view, Window Pry enables you to exclude any untitled or hidden window from the tree structure.

**Conclusion** Window Pry is an intuitive and multi-purpose tool that enables you to extract metadata from window handles. As a

developer, you can use the software in order to help you define a program's errors and create a handle that manages that particular irregularity. This way, you can offer the end-user a solution as well as help them avoid memory dumps. 25 Best Free Windows

Visit: The program computes radii of curvature of a smooth surface. You can select a plane with a few clicks of the mouse, and the program calculates the radius of curvature of the surface in points (x,y). You can also define the contour of the surface as a polygon or a surface defined by a set of points. The program also calculates the surface area. The program accepts the radius and defines the curvature of the surface for a variety of surfaces (spherical, cylindrical, elliptical) according to the formula: Radius of curvature =  $(r/R)(k_1/k_2)(1/(k_2x_1 - k_1x_2))$  where r = Distance from the center of curvature, R = Radius of the curvature, k1 = First curvature (the direction of the normal vector), and k2 = Second curvature (the direction of the tangent vector) The program is a simple, interactive calculator that can perform the calculations. You can select the type of surface you are working with in the upper left

---

corner. A quick explanation of the program follows. The background picture shows a method for finding the curvature of a plane. The letters A, B, C, and D denote points on the curve defined by the surface, and the letter F denotes the center of curvature. The text on the bottom of the screen explains the surface being worked on. Click on the surface to see the algorithm in action. The color of the text changes as you define the location of the points and the center of curvature. The surface area calculation is explained in the text on the bottom of the screen. The area of the surface is calculated by first adding up the areas of each triangle formed by a series of points. The result is displayed at the bottom of the screen. 77a5ca646e
